## 1 `assign_mcl.lean`

`assign_mcl.assign_rel`

Show

## 2 `aux.lean`

## 3 `mcl.lean`

## 4 `parlang.lean`

`parlang.kernel`

Kernel of a parallel program.

The general idea is to not have explicit expressions, but use Lean functions to compute values. What we are explicit global loads and stores.

$\Sigma$  is constructor where the second argument may depend on the type of the first (in this case `i`). Can be constructed using `<...>`

`parlang.memory`

Memory view

`parlang.thread_state`

Thread state including a global memory view, the list of loads and stores tells what should differ between different threads.

`parlang.state`

Global program state

`parlang.exec_state`

Execute a kernel on a global state, i.e. a list of threads

## 5 `rel_hoare.lean`
